Team Vibe Strike — Domain: E-Commerce Operations

Problem statement: "Order & Inventory Engine"

A mid-size retailer needs a backend system to manage orders and stock in real time.

Use Cases:

1. **As a customer, I want to browse products and place an order**, so that I can buy what I need. The system must reflect real-time stock — if two customers try to buy the last unit at once, only one order should succeed.
2. **As a customer, I want discounts and coupon codes applied automatically at checkout**, so that promotions are honored without manual intervention.
3. **As an ops manager, I want to see current inventory levels and be alerted when something is low-stock**, so that I can reorder before we run out.
4. **As an ops manager, I want to track any order's status from placed to delivered**, so that I can answer a customer's "where's my order" question in seconds.

Deliverable: A working system, end to end, that a live user (playing "customer") and a live ops manager could actually operate — plus an OpenAPI spec for the API.

Criterion	Pts	What to look for
Functionality — use case coverage	15	All required use cases work correctly when demoed live, including the Claude-API-powered one

Architecture diagram	10	Accurately reflects what was actually built (not an idealized version) and is clear enough that someone outside the team could understand the system from it
Frontend / usability	10	A real user could operate the app without narration from the team; it looks like something a client would accept
Effective use of Claude Code	10	Used across the stack (not just one layer), and the team can explain how what it built works when asked
Overall integration & polish	5	The system runs live as one coherent product, without the team patching bugs mid-demo
